Abstract.

We study search by quantum walk on a finite two dimensional grid. The algorithm of Ambainis, Kempe, Rivosh [AKR05] $O(\sqrt{N} \log N)$ steps and finds a marked location with probability $O(1/\log N)$ for grid of size $\sqrt{N} \times \sqrt{N}$. This probability is small, thus [AKR05] needs amplitude amplification to get $\Theta(1)$ probability. The amplitude amplification adds an additional $O(\sqrt{\log N})$ factor to the number of steps, making it $O(\sqrt{N} \log N)$.

In this paper, we show that despite a small probability to find a marked location, the probability to be within $O(\sqrt{N})$ neighbourhood (at $O(\sqrt[4]{N})$ distance) of the marked location is $\Theta(1)$. This allows to skip amplitude amplification step and leads to $O(\sqrt{\log N})$ speed-up.

We describe the results of numerical experiments, supporting this idea, and we prove this fact analytically.

1 Introduction

Quantum walks are quantum counterparts of random walks [Amb03, Kem03]. They have been useful to design quantum algorithms for a variety of problems [CC+03, Amb04, Sze04, AKR05, MSS05, BS06]. In many of those applications, quantum walks are used as a tool for search.

To solve a search problem using quantum walks, we introduce marked locations corresponding to elements of the search space we want to find. We

*This research has been supported by the European Social Fund within the projects “Support for Doctoral Studies at University of Latvia”, 1DP/1.1.1.2.0/09/APIA/VIAA/044, FP7 Marie Curie International Reintegration Grant PIRG02-GA-2007-224886 and FP7 FET-Open project QCS.

then perform a quantum walk on search space with one transition rule at unmarked locations and another transition rule at marked locations. If this process is set up properly, it leads to a quantum state in which marked locations have higher probability than unmarked ones. This method of search using quantum walks was first introduced in [SKW03] and has been used many times since then.

In this paper we study the quantum walks on a finite two-dimensional grid according to [AKR05]. It has been shown that after $O(\sqrt{N \log N})$ steps a quantum walk on 2D grid with one or two marked locations reaches a state that is significantly different from the state of a quantum walk with no marked location. If this state is measured the probability to obtain a marked location is $O(1/\log N)$. This probability is small, thus [AKR05] uses amplitude amplification. Amplitude amplification adds an additional $O(\sqrt{\log N})$ factor to the number of steps, making it $O(\sqrt{N \log N})$.

In case of two-dimensional grid it is logical to examine not only the marked location but also its close neighbourhood. We show that despite small probability to find marked location, the probability to be within $O(\sqrt{N})$ neighbourhood, i.e. at $O(\sqrt[4]{N})$ distance from the marked location, is $\Theta(1)$. This allows us to skip amplitude amplification step and leads to $O(\sqrt{\log N})$ speed-up.

The same speed-up has been already achieved by other research groups. Their approaches to this problem are based on modification of the original algorithm [Tul08] or both the algorithm and the structure of the grid [KM+10].

Our result shows that the improvement of the running time to $O(\sqrt{N \log N})$ can be achieved without any modifications to the quantum algorithm, with just a simple classical post-processing.

2 Quantum walks in two dimensions

Suppose we have N items arranged on a two dimensional lattice of size $\sqrt{N} \times \sqrt{N}$. We will also denote $n = \sqrt{N}$. The locations on the lattice are labelled by their x and y coordinate as (x, y) for $x, y \in \{0, \dots, n-1\}$. We assume that the grid has periodic boundary conditions. For example, going right from a location $(n-1, y)$ on the right edge of the grid leads to the location $(0, y)$ on the left edge of the grid.

To define a quantum walk, we add an additional "coin" register with four states, one for each direction: $|\uparrow\rangle$, $|\downarrow\rangle$, $|\leftarrow\rangle$ and $|\rightarrow\rangle$. At each step we perform a unitary transformation on the extra register and then evolve

the system according to the state of the coin register. Thus, the basis states of quantum walk are $|i, j, d\rangle$ for $i, j \in \{0, \dots, n-1\}$, $d \in \{\uparrow, \downarrow, \Leftarrow, \Rightarrow\}$ and the state of quantum walk is given by:

$$|\psi(t)\rangle = \sum_{i,j} (\alpha_{i,j,\uparrow} |i, j, \uparrow\rangle + \alpha_{i,j,\downarrow} |i, j, \downarrow\rangle + \alpha_{i,j,\Leftarrow} |i, j, \Leftarrow\rangle + \alpha_{i,j,\Rightarrow} |i, j, \Rightarrow\rangle) \quad (1)$$

A step of the coined quantum walk is performed by first applying $I \times C$, where C is unitary transform on the coin register. The most often used transformation on the coin register is the Grover's diffusion transformation D :

$$D = \frac{1}{2} \begin{pmatrix} -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & 1 \\ 1 & 1 & -1 & 1 \\ 1 & 1 & 1 & -1 \end{pmatrix} \quad (2)$$

Then, we apply the shift transformation S :

$$\begin{aligned} |i, j, \uparrow\rangle &\rightarrow |i, j-1, \downarrow\rangle \\ |i, j, \downarrow\rangle &\rightarrow |i, j+1, \uparrow\rangle \\ |i, j, \Leftarrow\rangle &\rightarrow |i-1, j, \Rightarrow\rangle \\ |i, j, \Rightarrow\rangle &\rightarrow |i+1, j, \Leftarrow\rangle \end{aligned} \quad (3)$$

Notice that after moving to an adjacent location we change the value of the direction register to the opposite. This is necessary for the quantum walk algorithm of [AKR05] to work.

We start quantum walk in the state

$$|\psi(0)\rangle = \frac{1}{2\sqrt{N}} \sum_{i,j} (|i, j, \uparrow\rangle + |i, j, \downarrow\rangle + |i, j, \Leftarrow\rangle + |i, j, \Rightarrow\rangle)$$

It can be easily verified that the state of the walk stays unchanged, regardless of the number of steps. To use quantum walk as a tool for search, we "mark" some locations. In unmarked locations, we apply the same transformations as above. In marked locations, we apply $-I$ instead of D as the coin flip transformation. The shift transformation remains the same in both marked and unmarked locations.

If there are marked locations, the state of this process starts to deviate from $|\psi(0)\rangle$. It has been shown [AKR05] that after $O(\sqrt{N \log N})$ steps the inner product $\langle \psi(t) | \psi(0) \rangle$ becomes close to 0.

In case of one or two marked locations [AKR05] algorithm finds a marked location with $O(1/\log N)$ probability. For multiple marked locations this is not always the case. There exist marked location configurations for which quantum walk fails to find any of marked locations [AR08].

3 Results

In this paper we examine a single marked location case only. However, we note that numerical experiments give very similar results in the case of multiple marked locations.

Suppose we have an $\sqrt{N} \times \sqrt{N}$ grid with one marked location. The [AKR05] algorithm takes $O(\sqrt{N} \log N)$ steps and finds the marked location with $O(1/\log N)$ probability. The algorithm then uses amplitude amplification to get $\Theta(1)$ probability. The amplitude amplification adds an additional $O(\sqrt{\log N})$ factor to the number of steps, making it $O(\sqrt{N} \log N)$.

Performing numerical experiments with [AKR05] algorithm, we have noticed that probability to be close to the marked location is much higher than probability to be far from the marked location. Figure 1 shows probabil-

Figure 1: Probability by distance, one marked location, grid size 1024×1024 , normal scale.

ity distribution by distance from the marked location for 1024×1024 grid. Figure 2 shows the same probability distribution on logarithmic scale.

Figure 2: Probability by distance, one marked location, grid size 1024×1024 , logarithmic scale.

We have measured the probability within $O(\sqrt{N})$ neighbourhood of the marked location (at $O(\sqrt[4]{N})$ distance) for different grid sizes (figure 3) and have made the following conjecture: ¹

Hypothesis 1 *The probability to be within $O(\sqrt{N})$ neighbourhood, i.e. at $O(\sqrt[4]{N})$ distance, of the marked location is $\Theta(1)$.*

In the next section we present a strict analytical proof of the conjecture, which in the further discussion will be referred as theorem 1.

The theorem allows us to replace amplitude amplification with a classical post processing step. After the measurement we classically check $O(\sqrt{N})$ neighbourhood of the outcome. This requires extra $O(\sqrt{N})$ steps but removes $O(\sqrt{\log N})$ factor. Therefore, the running time of the algorithm stays $O(\sqrt{N \log N})$.

¹Another logical choice of the size of the neighbourhood would be $O(\sqrt{N \log N})$ - the number of steps of [AKR05] algorithm.

Figure 3: Probability to be within $\sqrt{N}$ neighbourhood from the marked location.

Before going into details of the proof, we would like to give the reader some understanding of the final state of the algorithm (state before the measurement). Denote $Pr[0]$ the probability to find a marked location and $Pr[R]$ the probability to be at distance R from the marked location. For small R values ($R \ll \sqrt{N}$), the numerical experiments indicate that:

$$Pr[R] \approx \frac{Pr[0]}{R^2}$$

There are $4R$ points at the distance R from the marked location (we use Manhattan or L_1 distance). Thus, the total probability to be within $\sqrt{N}$ neighbourhood of the marked location is:

$$S = \sum_{R=1}^{\sqrt[4]{N}} 4R \times O\left(\frac{Pr[0]}{R^2}\right) = Pr[0] \times \sum_{R=1}^{\sqrt[4]{N}} O\left(\frac{1}{R}\right) = Pr[0] \times O(\log N).$$

As probability to find the marked location is $O(1/\log N)$, we have

$$S = O\left(\frac{1}{\log N}\right) \times O(\log N) = \text{const.}$$

4 Proofs

In this section, we show

Theorem 1 *We can choose $t = O(\sqrt{N \log N})$ so that, if we run a quantum walk with one marked location (i, j) for t steps and measure the final state, the probability of obtaining a location (i', j') with $|i - i'| \leq N^\epsilon$ and $|j - j'| \leq N^\epsilon$ as the measurement result is $\Omega(\epsilon)^2$.*

The proof of Theorem 1 consists of two steps. First, in Lemma 1, we derive an approximation for the state of quantum walk, at the time $t = O(\sqrt{N \log N})$ when the state of quantum walk has the biggest difference from the starting state. Then, in section 5, we use this approximation to derive our main result, via a sequence of algebraic transformations and approximations.

4.1 Approximation of the state of the quantum walk

Let

$$|\psi\rangle = \sum_{j=0}^{\sqrt{N}-1} \sum_{j'=0}^{\sqrt{N}-1} \sum_d \alpha_{j,j',d}^t |j, j', d\rangle$$

be the state of the quantum walk after t steps.

Lemma 1 *We can choose $t = O(\sqrt{N \log N})$ so that for any set*

$$S \subseteq \{0, \dots, \sqrt{N} - 1\}^2,$$

we have

$$\sum_{(j,j') \in S} |\alpha_{j,j',\uparrow}^t|^2 \geq C^2 \sum_{(j,j') \in S} (f(j, j') - f(j-1, j'))^2 + o(1)$$

where

$$f(j, j') = \sum_{(k,l) \neq (0,0)} \frac{1}{2 - \cos \frac{2k\pi}{\sqrt{N}} - \cos \frac{2l\pi}{\sqrt{N}}} w^{kj+lj'},$$

$$w = e^{\frac{2\pi i}{\sqrt{N}}} \text{ and } C = \Theta\left(\frac{1}{N\sqrt{\log N}}\right).$$

²Here, $|i - i'| \leq N^\epsilon$ and $|j - j'| \leq N^\epsilon$ should be interpreted “modulo N ”: $|i - i'| \leq N^\epsilon$ if $(i - i') \bmod N \in \{-N^\epsilon, -N^\epsilon + 1, \dots, N^\epsilon\}$.

Proof: We will repeatedly use the following lemma.

Lemma 2 [BV] Let $|\psi\rangle = \sum_{i=1}^m \alpha_i |i\rangle$ and $|\psi'\rangle = \sum_{i=1}^m \beta_i |i\rangle$. Then, for any set $S \subseteq \{1, 2, \dots, m\}$,

$$\sum_{i \in S} ||\alpha_i|^2 - |\beta_i|^2| \leq 2\|\psi - \psi'\|.$$

We recast the algorithm for search on the grid as an instance of an *abstract search algorithm* [AKR05]. An abstract search algorithm consists of two unitary transformations U_1 and U_2 and two states $|\psi_{start}\rangle$ and $|\psi_{good}\rangle$. We require the following properties:

1. $U_1 = I - 2|\psi_{good}\rangle\langle\psi_{good}|$ (in other words, $U_1|\psi_{good}\rangle = -|\psi_{good}\rangle$ and, if $|\psi\rangle$ is orthogonal to $|\psi_{good}\rangle$, then $U_1|\psi\rangle = |\psi\rangle$);
2. $U_2|\psi_{start}\rangle = |\psi_{start}\rangle$ for some state $|\psi_{start}\rangle$ with real amplitudes and there is no other eigenvector with eigenvalue 1;
3. U_2 is described by a real unitary matrix.

The abstract search algorithm applies the unitary transformation $(U_2U_1)^T$ to the starting state $|\psi_{start}\rangle$. We claim that under certain constraints its final state $(U_2U_1)^T|\psi_{start}\rangle$ has a sufficiently large inner product with $|\psi_{good}\rangle$.

For the quantum walk on $\sqrt{N} \times \sqrt{N}$ grid,

$$|\psi_{good}\rangle = \frac{1}{2}|i, j, \uparrow\rangle + \frac{1}{2}|i, j, \downarrow\rangle + \frac{1}{2}|i, j, \Leftarrow\rangle + \frac{1}{2}|i, j, \Rightarrow\rangle,$$

where i, j is the marked location and

$$|\psi_{start}\rangle = \frac{1}{2\sqrt{N}} \sum_{i,j=0}^{\sqrt{N}-1} (|i, j, \uparrow\rangle + |i, j, \downarrow\rangle + |i, j, \Leftarrow\rangle + |i, j, \Rightarrow\rangle).$$

Since U_2 is described by a real-value matrix, its eigenvectors (with eigenvalues that are not 1 or -1) can be divided into pairs: $|\Phi_j^+\rangle$ and $|\Phi_j^-\rangle$, with eigenvalues $e^{i\theta_j}$ and $e^{-i\theta_j}$, respectively. In the case of the walk on the 2-dimensional grid, these eigenvalues were calculated in Claim 6 of [AKR05]:

Claim 1 *Quantum walk on the 2-dimensional grid with no marked locations has $N - 1$ pairs of eigenvalues $e^{-i\theta_j}$ that are not equal to 1 or -1. These values can be indexed by pairs (k, l) , $k, l \in \{0, 1, \dots, \sqrt{N} - 1\}$, $(k, l) \neq (0, 0)$. The corresponding eigenvalues are equal to $e^{\pm i\theta_{k,l}}$, where $\theta_{k,l}$ satisfies $\cos \theta_{k,l} = \frac{1}{2}(\cos \frac{2\pi k}{\sqrt{N}} + \cos \frac{2\pi l}{\sqrt{N}})$.*

We use $|\Phi_{k,l}^+\rangle$ and $|\Phi_{k,l}^-\rangle$ to denote the corresponding eigenvectors. According to [MPA10, pages 3-4], these eigenvectors are equal to $|\Phi_{k,l}^+\rangle = |\xi_k\rangle \otimes |\xi_l\rangle \otimes |v_{k,l}^+\rangle$, $|\Phi_{k,l}^-\rangle = |\xi_k\rangle \otimes |\xi_l\rangle \otimes |v_{k,l}^-\rangle$ where $|\xi_k\rangle = \sum_{i=0}^{\sqrt{N}-1} w^{ki} \frac{1}{\sqrt[4]{N}} |i\rangle$,

$$|v_{k,l}^+\rangle = \frac{i}{2\sqrt{2}\sin\theta_{k,l}} \begin{bmatrix} e^{-i\theta_{k,l}} - w^k \\ e^{-i\theta_{k,l}} - w^{-k} \\ e^{-i\theta_{k,l}} - w^l \\ e^{-i\theta_{k,l}} - w^{-l} \end{bmatrix}, \quad |v_{k,l}^-\rangle = \frac{i}{2\sqrt{2}\sin\theta_{k,l}} \begin{bmatrix} w^k - e^{i\theta_{k,l}} \\ w^{-k} - e^{i\theta_{k,l}} \\ w^l - e^{i\theta_{k,l}} \\ w^{-l} - e^{i\theta_{k,l}} \end{bmatrix}.$$

The order of directions for the coin register is: $|\Downarrow\rangle, |\Uparrow\rangle, |\Rightarrow\rangle, |\Leftarrow\rangle$. The sign of $|v_{k,l}^-\rangle$ has been adjusted so that

$$\frac{1}{\sqrt{2}}|\Phi_{k,l}^+\rangle + \frac{1}{\sqrt{2}}|\Phi_{k,l}^-\rangle = |\xi_k\rangle \otimes |\xi_l\rangle \otimes |\psi_0\rangle \quad (4)$$

where $|\psi_0\rangle = \frac{1}{2}|\Downarrow\rangle + \frac{1}{2}|\Uparrow\rangle + \frac{1}{2}|\Rightarrow\rangle + \frac{1}{2}|\Leftarrow\rangle$.

We can assume that $|\psi_{good}\rangle = |0\rangle \otimes |0\rangle \otimes |\psi_0\rangle$. This gives us an expression of $|\psi_{good}\rangle$ in terms of the eigenvectors of U_2 :

$$\begin{aligned} |\psi_{good}\rangle &= \frac{1}{\sqrt{N}} \sum_{k,l} |\xi_k\rangle \otimes |\xi_l\rangle \otimes |\psi_0\rangle \\ &= \frac{1}{\sqrt{N}} |\psi_{start}\rangle + \sum_{(k,l) \neq (0,0)} \left(\frac{1}{\sqrt{2N}} |\Phi_{k,l}^+\rangle + \frac{1}{\sqrt{2N}} |\Phi_{k,l}^-\rangle \right). \end{aligned}$$

Using the results from [AKR05], we can transform this into an expression for the final state of our quantum search algorithm. According to the first big equation in the proof of Lemma 5 in [AKR05], after $t = O(\sqrt{N \log N})$ steps, we get a final state $|\psi\rangle$ such that $\| |\psi\rangle - |\phi_{final}\rangle \| = o(1)$, where $|\phi_{final}\rangle = \frac{|\phi'_{final}\rangle}{\|\phi'_{final}\|}$ and

$$|\phi'_{final}\rangle = \frac{2}{\sqrt{N}} |\psi_{start}\rangle + \frac{1}{\sqrt{2N}} \sum_{(k,l) \neq (0,0)} a_{k,l} |\Phi_{k,l}^+\rangle + b_{k,l} |\Phi_{k,l}^-\rangle \quad (5)$$

and

$$\begin{aligned} a_{k,l} &= 1 + \frac{i}{2} \cot \frac{\alpha + \theta_{k,l}}{2} + \frac{i}{2} \cot \frac{-\alpha + \theta_{k,l}}{2}, \\ b_{k,l} &= 1 + \frac{i}{2} \cot \frac{\alpha - \theta_{k,l}}{2} + \frac{i}{2} \cot \frac{-\alpha - \theta_{k,l}}{2}. \end{aligned}$$

We now replace $\sum_{(j,j') \in S} |\alpha_{j,j',d}^t|^2$ by the corresponding sum of squares of amplitudes for the state $|\phi_{final}\rangle$. By Lemma 2, this changes the sum by an amount that is $o(1)$.

From [AKR05], we have $\alpha = \Theta(\frac{1}{\sqrt{N \log N}})$, $\min \theta_{k,l} = \Theta(\frac{1}{\sqrt{N}})$ and $\max \theta_{k,l} = \frac{\pi}{2} \Theta(\frac{1}{\sqrt{N}})$. Hence, we have $\pm \alpha + \theta_{k,l} = (1 + o(1))\theta_{k,l}$ and we get

$$\begin{aligned} |\phi'_{final}\rangle &= \frac{1}{\sqrt{N}} |\psi_{start}\rangle + \sum_{(k,l) \neq (0,0)} \frac{1}{\sqrt{2N}} \left(1 + i(1 + o(1)) \cot \frac{\theta_{k,l}}{2} \right) |\Phi_{k,l}^+\rangle + \\ &\quad \frac{1}{\sqrt{2N}} \left(1 - i(1 + o(1)) \cot \frac{\theta_{k,l}}{2} \right) |\Phi_{k,l}^-\rangle. \end{aligned} \quad (6)$$

This means that $\| |\psi_{final}\rangle - |\phi_{final}\rangle \| = o(1)$ where $|\psi_{final}\rangle = \frac{|\psi'_{final}\rangle}{\|\psi'_{final}\|}$ and

$$|\psi'_{final}\rangle = |\psi_{good}\rangle + \sum_{(k,l) \neq (0,0)} \frac{1}{\sqrt{2N}} i \cot \frac{\theta_{k,l}}{2} (|\Phi_{k,l}^+\rangle - |\Phi_{k,l}^-\rangle). \quad (7)$$

Again, we can replace a sum of squares of amplitudes for the state $|\phi_{final}\rangle$ by the corresponding sum for $|\psi_{final}\rangle$ and, by Lemma 2, the sum changes by an amount that is $o(1)$.

We now estimate the amplitude of $|j, j', \uparrow\rangle$ in $|\psi_{final}\rangle$. We assume that $(j, j') \neq (0, 0)$. Then, the amplitude of $|j, j', \uparrow\rangle$ in $|\psi_{good}\rangle$ is 0. Hence, we can evaluate the amplitude of $|j, j', \uparrow\rangle$ in

$$\sum_{(k,l) \neq (0,0)} \frac{1}{\sqrt{2N}} i \cot \frac{\theta_{k,l}}{2} (|\Phi_{k,l}^+\rangle - |\Phi_{k,l}^-\rangle) \quad (8)$$

and then divide the result by $\Theta(\sqrt{\log N})$, because $\|\psi'_{final}\| = \Theta(\sqrt{\log N})$.

From the definitions of $|\Phi_{k,l}^\pm\rangle$ and $|v_{k,l}^\pm\rangle$,

$$\frac{1}{\sqrt{2}} |v_{k,l}^+\rangle - \frac{1}{\sqrt{2}} |v_{k,l}^-\rangle = \frac{i}{4 \sin \theta_{k,l}} \begin{bmatrix} 2 \cos \theta_{k,l} - 2w^k \\ 2 \cos \theta_{k,l} - 2w^{-k} \\ 2 \cos \theta_{k,l} - 2w^l \\ 2 \cos \theta_{k,l} - 2w^{-l} \end{bmatrix}$$

Therefore, the amplitude of $|\uparrow\rangle$ in this state is $\frac{i}{2 \sin \theta_{k,l}} (\cos \theta_{k,l} - w^{-k})$. The amplitude of $|j\rangle$ in $|\xi_k\rangle$ is $\frac{1}{\sqrt{N}} w^{kj}$. The amplitude of $|j'\rangle$ in $|\xi_l\rangle$ is $\frac{1}{\sqrt{N}} w^{lj'}$. Therefore, the amplitude of $|j, j', \uparrow\rangle$ in $\frac{1}{\sqrt{2}} |\Phi_{k,l}^+\rangle - \frac{1}{\sqrt{2}} |\Phi_{k,l}^-\rangle$ is

$$\frac{1}{\sqrt{N}} w^{kj+lj'} \frac{i}{2 \sin \theta_{k,l}} (\cos \theta_{k,l} - w^{-k})$$

and the amplitude of $|j, j', \uparrow\rangle$ in (8) is

$$\frac{1}{\sqrt{2N}} \sum_{(k,l) \neq (0,0)} i \cot \frac{\theta_j}{2} \cdot \frac{i}{2 \sin \theta_{k,l}} (\cos \theta_{k,l} - w^{-k}) w^{kj+l j'}.$$

By using $\sin \theta_{k,l} = 2 \sin \frac{\theta_{k,l}}{2} \cos \frac{\theta_{k,l}}{2}$, we get that the amplitude of $|j, j', \uparrow\rangle$ is

$$\begin{aligned} & \frac{1}{\sqrt{2}} \sum_{(k,l) \neq (0,0)} \frac{1}{4N} \left(-\frac{\cos \theta_{k,l}}{\sin^2 \frac{\theta_{k,l}}{2}} w^{kj+l j'} + \frac{1}{\sin^2 \frac{\theta_{k,l}}{2}} w^{k(j-1)+l j'} \right) \\ &= \frac{1}{\sqrt{2}} \sum_{(k,l) \neq (0,0)} \frac{1}{4N} \left(2w^{kj+l j'} - \frac{1}{\sin^2 \frac{\theta_{k,l}}{2}} (w^{kj+l j'} - w^{k(j-1)+l j'}) \right), \quad (9) \end{aligned}$$

with the equality following from $\cos 2x = 1 - 2 \sin^2 x$.

We can decompose the sum into two sums, one over all the first components, one over all the second components. The first component of the sum in (9) is close to 0 and, therefore, can be omitted. Hence, we get that the amplitude of $|j, j', \uparrow\rangle$ in the unnormalized state $|\psi'_{final}\rangle$ can be approximated by

$$\frac{1}{\sqrt{2}} \sum_{(k,l) \neq (0,0)} \frac{1}{4N} \frac{1}{\sin^2 \frac{\theta_{k,l}}{2}} (-w^{kj+l j'} + w^{k(j-1)+l j'}) = \Theta\left(\frac{1}{N}\right) \cdot (f(j-1, j') - f(j, j')).$$

To obtain the amplitude of $|j, j', \uparrow\rangle$ in $|\psi_{final}\rangle$, this should be divided by $\|\psi'_{final}\|$ which is of the order $\Theta(\sqrt{\log N})$. This implies Lemma 1. $\blacksquare$

5 Bounds on the probability of being close to the marked location

We start by performing some rearrangements in the expression $f(j, j')$.

Let $n = \sqrt{N}$ and S be the set of all pairs (k, l) such as $k, l \in \{0, 1, \dots, n-1\}$, except for $(0, 0)$. We consider

$$\begin{aligned} f(j, j') &= \sum_{(k,l) \in S} \frac{1}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}} w^{kj+l j'} \\ &= \sum_{(k,l) \in S} \frac{\cos \frac{2(kj+l j')\pi}{n} + \sin \frac{2(kj+l j')\pi}{n} i}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}}. \quad (10) \end{aligned}$$

Since the cosine function is periodic with period 2π , we have $\cos \frac{2l\pi}{n} = \cos \frac{2(l-N)\pi}{n}$. Hence, we can replace the summation over S by the summation over

$$S' = \left\{ (k, l) \mid k, l \in \left\{ -\left\lfloor \frac{n}{2} \right\rfloor, 1, \dots, \left\lfloor \frac{n}{2} - 1 \right\rfloor \right\} \right\} \setminus \{(0, 0)\}.$$

This implies that the imaginary part of (10) cancels out because terms in the sum can be paired up so that, in each pair, the imaginary part in both terms has the same absolute value but opposite sign. Namely:

- If none of $k, l, -k$ and $-l$ is equal to $\frac{n}{2}$, we pair up (k, l) with $(-k, -l)$.
- If none of k and $-k$ is equal to 0 or $\frac{n}{2}$, we pair up $(-\frac{n}{2}, k)$ with $(-\frac{n}{2}, -k)$ and $(k, -\frac{n}{2})$ with $(-k, -\frac{n}{2})$.
- The terms $(-\frac{n}{2}, 0)$, $(0, -\frac{n}{2})$ and $(-\frac{n}{2}, -\frac{n}{2})$ are left without a pair. This does not affect the argument because the imaginary part is equal to 0 in those terms.

Hence, we have

$$f(j, j') = \sum_{(k, l) \in S'} \frac{\cos \frac{2(kj + lj')\pi}{n}}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}}.$$

We define a function $g(j, j') = f(j, j') - f(j - 1, j')$. By Lemma 1, $Cg(j, j')$ is a good approximation for the amplitude of $|j, j', \uparrow\rangle$ in the state of the quantum walk after $t = O(\sqrt{N \log N})$ steps.

Lemma 3

$$\sum_{0 < j', j < M} g^2(j, j') = \Omega(n^2 \ln M)$$

where $M = n^\epsilon$ and $\epsilon = \Omega(1)$, and $\epsilon = 1 - \Omega(1)$.

Together with Lemma 1, this implies that the sum of amplitudes of $|j, j', \uparrow\rangle$, $0 < j', j < M$ is $\Omega(\frac{\log M}{\log n}) - o(1)$. Since $\frac{\log M}{\log N} = \epsilon$, this would complete the proof of Theorem 1.

Proof: [of Lemma 3] We introduce a function

$$R(M', M'', k) = \sum_{l=M'+1}^{M''} g^2(l, k)$$

where $M'' > M' > k$ and $M'' = \alpha M'$ for some α .

Claim 2 $|f(j, j') - \frac{n^2}{2\pi^2} f'(j, j')| = O(n^2)$ where

$$f'(j, j') = \sum_{(k, l) \in S'} \frac{\cos \frac{2(kj + lj')\pi}{n}}{k^2 + l^2}.$$

Claim 3 Let $j' = j\beta$ where $0 < \beta \leq 1$ and $j = n^\epsilon$, and $\epsilon = \Omega(1)$, and $\epsilon = 1 - \Omega(1)$.

The following equality holds:

$$f'(j, j') = \frac{\pi}{2} \ln \frac{n}{j} + O(1).$$

Given these two claims, we now complete the proof of Lemma 3. From the inequality of quadratic and arithmetic means, we get

$$\begin{aligned} R(M', M'', k) &\geq \frac{(f(M'', k) - f(M', k))^2}{M'' - M'} \\ &= \frac{\left(\frac{n^2}{4\pi} \ln \frac{n}{M''} - \frac{n^2}{4\pi} \ln \frac{n}{M'} + O(n^2)\right)^2}{M'' - M'} \\ &= \frac{\left(\frac{n^2}{4\pi} \ln \alpha + O(n^2)\right)^2}{(\alpha - 1)M'} \\ &= \frac{\Omega(n^2)}{M'} \end{aligned}$$

where the first equality follows from $M'', M' > k$ and Claims 2 and 3. The last equality holds if we choose an α large enough that $\frac{n^2}{4\pi} \ln \alpha + O(n^2) = \Omega(n^2)$.

We introduce a notation

$$P(M') = \sum_{l=0}^{M'-1} R(M', \alpha M', l).$$

From $R(M', M'', k) = \frac{\Omega(n^2)}{M'}$ we get $P(M') = \Omega(n^2)$. We obtain the following lower bound:

$$\sum_{0 < j', j < M} g^2(j, j') > \sum_{0 < j' < j < M} g^2(j, j')$$

$$> \sum_{l=1}^{\log_{\alpha} \sqrt{M}} P\left(\frac{M}{\alpha^l}\right) = \Omega\left(n^2 \log_{\alpha} \sqrt{M}\right) = \Omega(n^2 \ln M).$$

■

Proof: [of Claim 2]

We have

$$\begin{aligned} & |f(j, j') - \frac{n^2}{2\pi^2} f'(j, j')| \\ & \leq \sum_{(k, l) \in S'} \left| \cos \frac{2(kj + lj')\pi}{n} \right| \cdot \left| \frac{1}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}} - \frac{n^2}{2\pi^2(k^2 + l^2)} \right|. \end{aligned}$$

The claim now follows from $|S'| = n^2 - 1$, $|\cos x| \leq 1$ and

$$\left| \frac{1}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}} - \frac{n^2}{2\pi^2(k^2 + l^2)} \right| \leq \frac{1}{2}.$$

To prove the last inequality, we first rewrite

$$\frac{1}{2 - \cos \frac{2k\pi}{n} - \cos \frac{2l\pi}{n}} = \frac{1}{2(\sin^2 \frac{k\pi}{n} + \sin^2 \frac{l\pi}{n})}.$$

We have $x - \frac{x^3}{6} \leq \sin x \leq x$ for all $x \in [0, \pi]$. This implies $x^2 - \frac{x^4}{3} \leq \sin^2 x \leq x^2$. Hence, we have

$$\begin{aligned} & \left| \frac{1}{2(\sin^2 \frac{k\pi}{n} + \sin^2 \frac{l\pi}{n})} - \frac{1}{2((\frac{k\pi}{n})^2 + (\frac{l\pi}{n})^2)} \right| = \frac{(\frac{k\pi}{n})^2 + (\frac{l\pi}{n})^2 - (\sin^2 \frac{k\pi}{n} + \sin^2 \frac{l\pi}{n})}{2((\frac{k\pi}{n})^2 + (\frac{l\pi}{n})^2)(\sin^2 \frac{k\pi}{n} + \sin^2 \frac{l\pi}{n})} \\ & \leq \frac{(\frac{k\pi}{n})^4 + (\frac{l\pi}{n})^4}{6((\frac{k\pi}{n})^2 + (\frac{l\pi}{n})^2) \left((\frac{k\pi}{n})^2 + (\frac{l\pi}{n})^2 - \frac{(\frac{k\pi}{n})^4 + (\frac{l\pi}{n})^4}{3} \right)} \leq \frac{1}{2} \end{aligned}$$

where the last inequality follows from

$$\frac{a^2 + b^2}{(a + b) \left(a + b - \frac{a^2 + b^2}{3} \right)} \leq 3$$

which holds for $0 \leq a, b \leq (\frac{\pi}{2})^2$.

■

Proof: [of Claim 3]

We will use the notation $\alpha = \frac{2\pi}{n}$.

The following equalities hold

$$\begin{aligned}
\sum_{(k,l) \in S'} \frac{\cos \alpha(kj + lj')}{k^2 + l^2} &= \sum_{(k,l) \in S'} \frac{\cos \alpha j(k + l\beta)}{k^2 + l^2} \\
&= \sum_{\substack{k + l\beta \leq n \\ k, l \in Z^{0+} \\ (k,l) \neq (0,0)}} \frac{\cos \alpha j(k + l\beta)}{k^2 + l^2} + O(1). \tag{11}
\end{aligned}$$

The last equality holds because it lacks some summands, with absolute value of their sum bounded above by

$$\sum_{\substack{(k,l) \in S' \\ k + l > n}} \frac{1}{k^2 + l^2} = O(1).$$

It also has some new summands, with absolute value of their sum bounded above by

$$\sum_{\substack{l > n \\ 0 < k < n \\ k, l \in Z^{0+}}} \frac{1}{k^2 + l^2} = O(1).$$

We will use the notation $k' = k + \lceil l\beta \rceil - l\beta$. We replace the sum (11) (without the asymptotic) with

$$\sum_{\substack{k + l\beta \leq n \\ k, l \in Z^{0+} \\ (k,l) \neq (0,0)}} \frac{\cos \alpha j(k' + l\beta)}{k^2 + l^2}. \tag{12}$$

The error because of the replacement is

$$2\pi n^{\epsilon-1} \sum_{\substack{k + l\beta \leq n \\ k, l \in Z^{0+} \\ (k,l) \neq (0,0)}} \frac{1}{k^2 + l^2} \leq 2\pi n^{\epsilon-1} \sum_{\substack{k, l \in Z^{0+} \\ (k,l) \neq (0,0) \\ 0 \leq k \leq n \\ l \geq 0}} \frac{1}{k^2 + l^2}$$

$$= 2\pi n^{\epsilon-1} O(\ln n) = o(1)$$

where we used the fact that $|\cos \alpha j(k' + l\beta) - \cos \alpha j(k + l\beta)| \leq 2\pi n^{\epsilon-1}$.

We replace the sum (12) with

$$\sum_{\substack{k+l\beta \leq n \\ k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{\cos \alpha j(k' + l\beta)}{(k')^2 + l^2}. \quad (13)$$

The error of the last replacement is

$$\begin{aligned} & \left| \sum_{\substack{k+l\beta \leq n \\ k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \left(\frac{\cos \alpha j(k' + l\beta)}{(k')^2 + l^2} - \frac{\cos \alpha j(k + l\beta)}{k^2 + l^2} \right) \right| \\ & \leq \sum_{\substack{k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{(k')^2 - k^2}{(k^2 + l^2)^2} \leq \sum_{\substack{k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{2k + 1}{(k^2 + l^2)^2} \\ & \leq 3 \sum_{\substack{k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{k + l}{(k^2 + l^2)^2} \leq 12 \sum_{\substack{k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{1}{(k + l)^3} = O(1). \end{aligned}$$

We replace the sum (13) with

$$\sum_{\substack{k+l\beta \leq n \\ k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \cos(\alpha j(k' + l\beta)) \frac{1}{\beta} \int_{-\frac{\beta}{2}}^{\frac{\beta}{2}} \frac{dt}{(k' - t)^2 + \left(l + \frac{t}{\beta}\right)^2}. \quad (14)$$

Because of the last replacement the error in a fixed summand is

$$\left| \frac{1}{(k')^2 + l^2} - \frac{1}{\beta} \int_{-\frac{\beta}{2}}^{\frac{\beta}{2}} \frac{dt}{(k' - t)^2 + \left(l + \frac{t}{\beta}\right)^2} \right| =$$

$$\left| \frac{1}{(k')^2 + l^2} - \frac{\arctan\left(\frac{k' + l\beta}{(k')^2 + l^2 - \frac{1+\beta^2}{4}}\right)}{k' + l\beta} \right|.$$

By using $x - \frac{x^3}{3} < \arctan x < x$ that holds for all $x > 0$ we bound the error from above by

$$\left| \frac{-\frac{1+\beta^2}{4}}{((k')^2 + l^2)((k')^2 + l^2 - \frac{1+\beta^2}{4})} \right| + \left| \frac{\left(\frac{k' + l\beta}{(k')^2 + l^2 - \frac{1+\beta^2}{4}}\right)^3}{3(k' + l\beta)} \right|.$$

By using the inequalities $(k')^2 + l^2 \geq \frac{1}{2}(k' + l)^2$ and $(k')^2 + l^2 - \frac{1}{2} \geq \frac{1}{4}(k' + l)^2$ which hold if $k + l \geq 1$ and $k, l \in Z^{0+}$, and $0 < \beta \leq 1$, we obtain the following upper bound of the error:

$$\frac{4}{(k' + l)^4} + \frac{64}{3(k' + l)^4} = \frac{76}{3(k' + l)^4} \leq \frac{76}{3(k + l)^4}.$$

Thus, the error made in (14) can be bounded from above by

$$\sum_{\substack{k + l\beta \leq n \\ k, l \in Z^{0+} \\ (k, l) \neq (0, 0)}} \frac{76}{3(k + l)^4} = O(1).$$

We replace (14) with

$$\frac{1}{\beta} \sum_{s=1}^n \cos \alpha j s \int_0^s \frac{dk}{k^2 + \left(\frac{s-k}{\beta}\right)^2}.$$

We grouped summands with equal cosine arguments. We also altered integration limits to obtain an integral on the interval $[0, s]$. The error made in this step can be bounded from above by

$$\sum_{s=1}^n \frac{1}{s^2} = O(1).$$

By using $\int_0^s \frac{dk}{k^2 + \left(\frac{s-k}{\beta}\right)^2} = \frac{\beta\pi}{2s}$ we obtain the following sum:

$$\frac{\pi}{2} \sum_{s=1}^n \frac{\cos \alpha j s}{s}. \quad (15)$$

Proposition 1 *Let $j = n^\epsilon$ and $\epsilon = \Omega(1)$, and $\epsilon = 1 - \Omega(1)$.*

The following equality holds:

$$\sum_{k=1}^n \frac{\cos\left(\frac{2\pi}{n}jk\right)}{k} = (1 - \epsilon) \ln n + O(1).$$

Now Proposition 1 gives us that (15) is equal to

$$\frac{\pi}{2} \ln \frac{n}{j} + O(1).$$

■

Proof: [of Proposition 1]

We can rewrite the sum $\sum_{k=1}^n \frac{\cos\left(\frac{2\pi}{n}n^\epsilon k\right)}{k}$ in the following way:

$$\begin{aligned} & \sum_{k=1}^{\lfloor n^{1-\epsilon} \rfloor} \frac{\cos(2\pi n^{\epsilon-1}k)}{k} + \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \sum_{t=\lfloor n^{1-\epsilon}l \rfloor + 1}^{\lfloor n^{1-\epsilon}(l+1) \rfloor} \frac{\cos(2\pi n^{\epsilon-1}t)}{t} \\ & + \sum_{k=\lfloor n^{1-\epsilon} \lfloor n^\epsilon \rfloor \rfloor + 1}^n \frac{\cos(2\pi n^{\epsilon-1}k)}{k} \end{aligned} \quad (16)$$

Proposition 2

$$\sum_{k=1}^n \frac{\cos\left(\frac{2\pi}{n}k\right)}{k} = \ln n + O(1).$$

Proof:

The proposition follows from

$$\sum_{k=1}^n \frac{\cos\left(\frac{2\pi}{n}k\right)}{k} \leq \ln n + 1.$$

and

$$\sum_{k=1}^n \frac{\cos\left(\frac{2\pi}{n}k\right)}{k} \geq \sum_{k=1}^n \frac{1}{k} - \sum_{k=1}^n \frac{2\pi}{n} \geq \ln n - 2\pi$$

where the first inequality in the last expression follows from $\cos x \geq 1 - x$ which holds if $x \geq 0$.

■

From proposition 2 we get the following equality for the first big summand of (16):

$$\sum_{k=1}^{\lfloor n^{1-\epsilon} \rfloor} \frac{\cos(2\pi n^{\epsilon-1} k)}{k} = (1-\epsilon) \ln n + O(1).$$

We can also obtain the following bound for the third big summand of (16):

$$\left| \sum_{k=\lfloor n^{1-\epsilon} \rfloor + 1}^n \frac{\cos(2\pi n^{\epsilon-1} k)}{k} \right| < \frac{n^{1-\epsilon} + 1}{n - n^{1-\epsilon}} = o(1).$$

We replace the second big summand of (16) with

$$\sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \sum_{t=\lfloor n^{1-\epsilon} l \rfloor + 1}^{\lfloor n^{1-\epsilon} \rfloor + \lfloor n^{1-\epsilon} \rfloor} \frac{\cos(2\pi n^{\epsilon-1} t)}{t}. \quad (17)$$

The error because of the replacement is

$$\left| \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{\cos(2\pi n^{\epsilon-1} \lfloor n^{1-\epsilon} (l+1) \rfloor)}{\lfloor n^{1-\epsilon} (l+1) \rfloor} \right| < \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{1}{n^{1-\epsilon} l} = o(1)$$

which follows from the fact that the inequality $|\lfloor x \rfloor + \lfloor y \rfloor - \lfloor x+y \rfloor| \leq 1$ holds for all x and y .

We rewrite (17) as

$$\sum_{t=1}^{\lfloor n^{1-\epsilon} \rfloor} \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{\cos(2\pi n^{\epsilon-1} (\lfloor n^{1-\epsilon} l \rfloor + t))}{\lfloor n^{1-\epsilon} l \rfloor + t}.$$

We get rid of the floor function in the numerator of the last expression, thus, obtaining the following sum:

$$\sum_{t=1}^{\lfloor n^{1-\epsilon} \rfloor} \cos(2\pi n^{\epsilon-1} t) p(t) \quad (18)$$

where

$$p(t) = \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{1}{\lfloor n^{1-\epsilon} l \rfloor + t}.$$

Using the fact that $|\cos x - \cos y| \leq |x - y|$ holds for all x and y , we obtain that the cosine value because of the replacement changed at most by

$$|2\pi n^{\epsilon-1} (\lfloor n^{1-\epsilon} l \rfloor - n^{1-\epsilon} l)| \leq 2\pi n^{\epsilon-1}.$$

Thus, we obtain the following bound of the error of the replacement:

$$2\pi n^{\epsilon-1} \sum_{t=1}^{\lfloor n^{1-\epsilon} \rfloor} p(t) \leq 2\pi n^{\epsilon-1} n^{1-\epsilon} p(t) = o(1)$$

where we used

$$p(t) \leq \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{1}{n^{1-\epsilon} l} < \frac{\epsilon \ln n + 1}{n^{1-\epsilon}} = o(1).$$

To prove that the expression (18) is $O(1)$, first we will pair almost all of its summands so that the sum of cosine values in each pair is very close to 0.

Let $k(t) = \lfloor \frac{n^{1-\epsilon}}{2} \rfloor - t$ and $r(t) = \lfloor \frac{3n^{1-\epsilon}}{2} \rfloor - t$. We replace (18) with

$$\begin{aligned} & \sum_{t=3}^{\lfloor \frac{n^{1-\epsilon}}{4} \rfloor - 3} (\cos(2\pi n^{\epsilon-1} t) p(t) + \cos(2\pi n^{\epsilon-1} k(t)) p(k(t))) \\ & + \sum_{t=3}^{\lfloor n^{1-\epsilon} \rfloor - 3} (\cos(2\pi n^{\epsilon-1} t) p(t) + \cos(2\pi n^{\epsilon-1} r(t)) p(r(t))) \end{aligned} \quad (19)$$

where we removed some of the summands of (18). Let the number of the removed summands be $C = O(1)$. From $p(t) = o(1)$ we get that the error of the last replacement is $o(1)$.

Now we replace (19) with

$$\begin{aligned} & \sum_{t=3}^{\lfloor \frac{n^{1-\epsilon}}{4} \rfloor - 3} (\cos(2\pi n^{\epsilon-1} t) p(t) + \cos(\pi - 2\pi n^{\epsilon-1} t) p(k(t))) \\ & + \sum_{t=3}^{\lfloor n^{1-\epsilon} \rfloor - 3} (\cos(2\pi n^{\epsilon-1} t) p(t) + \cos(3\pi - 2\pi n^{\epsilon-1} t) p(r(t))) \end{aligned} \quad (20)$$

The error of the last replacement is $n^{1-\epsilon} \cdot 2\pi n^{\epsilon-1} \cdot o(1) = o(1)$ where the first factor is larger than the number of summands of the last sum; the second

factor is the maximum change in the value of the cosine function; the third factor is $p(t) = o(1)$.

Now we can bound the maximum value of (20) with

$$\begin{aligned} & \frac{\lfloor n^{1-\epsilon} \rfloor - C}{2} \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{1}{n^{1-\epsilon} l} - \frac{\lfloor n^{1-\epsilon} \rfloor - C}{2} \sum_{l=1}^{\lfloor n^\epsilon \rfloor - 1} \frac{1}{n^{1-\epsilon} (l+1)} \\ &= \frac{\lfloor n^{1-\epsilon} \rfloor - C}{2} \left(\frac{1}{n^{1-\epsilon}} - \frac{1}{n^{1-\epsilon} \lfloor n^\epsilon \rfloor} \right) = O(1). \end{aligned}$$
